Outline

1 Problem

2 Solution

Problem Statement

(Papoulis/Pillai Exercise 2-26) Show that a set S with n elements has

$$\frac{n(n-1)\dots(n-k+1)}{1.2\dots k} = \frac{n!}{k!(n-k)!} \quad (1)$$

subsets of k elements.

Solution

We begin by choosing any k elements of a set consisting of n elements. The first element can be chosen in n ways, the second in $n - 1$ ways, and so on. The k^{th} element can be chosen in $n - k + 1$ ways. However, the order of elements in a set does not matter. This gives a total of

$$\frac{n(n-1)\dots(n-k+1)}{1.2\dots k} \quad (2)$$

$$= \frac{n(n-1)\dots 1}{(1.2\dots k)(1.2\dots(n-k))} \quad (3)$$

$$= \frac{n!}{k!(n-k)!} = \binom{n}{k} \quad (4)$$

subsets containing k elements. Here, $0 \leq k \leq n$. The Python code `codes/10_1.py` verifies the identity.
